Tobacco and Cancer: Know the Risks

Tobacco smoke: a chemical cocktail
Tobacco smoke contains more than 7,000 chemicals, including 69 carcinogens or chemicals known to cause cancer.\(^1\) When you inhale cigarette smoke, these chemicals enter your lungs and spread through your body.\(^2\) Many of the chemicals in tobacco smoke are toxic and can cause damage to our cells leading to the development of diseases like cancer.\(^2\)

How does smoking tobacco cause cancer?
Carcinogens in tobacco smoke cause mutations in a gene called p53.\(^3\) The p53 gene is a tumour-suppressor helping prevent the formation and growth of cancers.\(^3\) Damage to the p53 gene leads to uncontrolled cell division: a precursor to cancer.\(^3\) Mutations in this gene are found in over 50% of all human tumours, including 60% of lung cancers.\(^4\)

Smoking causes cancer in many organs
Lung cancer was the first major disease to be causally linked to cigarette smoking with a number of landmark studies carried out in the 1950s and 1960s concluding that smoking is a cause of lung cancer.\(^5\) Since that time, the list of cancers linked to smoking has grown. There is now sufficient evidence that smoking is a risk factor for 16 types of cancer: lung, mouth (oral cavity), throat (pharynx), oesophagus, stomach, bowel, liver, pancreas, nasal cavity and sinuses, voice box (larynx), cervix, ovary, bladder, kidney, ureter and bone marrow (myeloid leukaemia).\(^5,6\)

Tobacco smoking is the most prevalent cause of cancer in humans, accounting for approximately 20%-30% of the total burden of cancer in Australia.\(^7\) In 2005, there were an estimated 11,308 new cases of cancer and 8,155 deaths from cancer that could be attributed to smoking, representing over 11% of cases and nearly 21% of cancer deaths.\(^8\)

Cancers associated with smoking

Cancer of the lung
The evidence that tobacco smoking causes lung cancer is undeniable.\(^2\) Lung cancer is one of the most common cancers in Australians men and women and the leading cause of cancer death in both sexes.\(^8\) In Australia, it is estimated that 88% of all lung cancer deaths in men and 75% in women (aged over 35) are due to active smoking.\(^2\)

Cancers of the mouth, pharynx, larynx and nasal cavity (and paranasal sinuses)
In Australia, 57% of oral cancers in men and 51% in women are caused by smoking.\(^5\) Oral cancers include cancers of the mouth and pharynx (throat). Tobacco smoking also causes 73% of laryngeal cancers in men and 66% in women.\(^8\) The use of alcohol in combination with tobacco increases the risk of head and neck cancers even further.\(^9\) Evidence suggests that smoking also causes sinus cancer and cancer of the nasal cavity.\(^5\)

Cancers of the oesophagus
It is estimated that smoking causes 54% of all oesophageal cancers in men and 46% in women.\(^8\)

Cancers of the bladder, kidney and ureter
Smoking causes cancer of the renal (kidney) cell, the renal pelvis, the ureter and the bladder.\(^2\) It is estimated that 43% of bladder cancers in men and 36% in women are caused by smoking.\(^8\) Approximately 28% of cancers of the kidney (except renal pelvis) in men and 21% in women are caused by smoking, while 55% of cancers of the renal pelvis in men and 48% in women are caused by smoking.\(^8\)
Cancer of the pancreas
Pancreatic cancer has a very poor prognosis with only about 5% of patients surviving the first five years after diagnosis.\(^{10}\) Approximately 24% of pancreatic cancers in men and 19% in women can be attributed to smoking.\(^{6}\)

Cancer of the stomach
It is estimated that 14% of stomach cancers in men and 11% in women are attributable to smoking.\(^{8}\)

Cancer of the liver
Studies show up to a 50% increase in risk of liver cancer for current smokers compared with non-smokers.\(^{2}\)

Cancer of the cervix and ovary
Women who smoke are at greater risk of developing cervical cancer with evidence to show certain cancers of the cervix such as squamous cell cervical carcinoma are linked to smoking.\(^{3,9}\) In Australia, 17% of deaths from cervical cancer in women aged 35 years and over could be attributable to smoking.\(^{7}\) Current smokers have a higher risk of ovarian cancer compared with ex-smokers and non-smokers.\(^{5}\)

Cancer of the colon and rectum (colorectal cancer)
Evidence suggests there is a causal relationship between smoking and colorectal cancer.\(^{1}\) Long-time smokers are more likely than non-smokers to have and die from colorectal cancer.\(^{11}\)

Acute myeloid leukaemia
Smoking is a cause of acute myeloid leukaemia. The risk increases with the number of cigarettes smoked and with the duration of smoking.\(^{2,5}\)
